INTEGRATED HANDHELD DATA PROCESSING DEVICE HAVING A SLIDING
FORM FACTOR

5

FIELD OF THE INVENTION

The present claimed invention relates to the field of handheld data processing devices. More particularly,
10 embodiments of the present claimed invention relate to an integrated handheld device having three components with a sliding configuration.

BACKGROUND ART

15

Over the years, many electronic instruments and devices have been sufficiently reduced in size to become portable, and in turn, small enough to be held and operated in the hand of the user. The advent of integrated circuits greatly increased
20 the number of devices that could achieve portability and handheld status, as well as increasing the functionality of such devices.

Today, handheld data processing devices include computers, video displays, audio players and recorders, laboratory instruments, telephones and other communications devices. In many cases, multiple functions may be integrated

5 into a single device such as in a telephone/audio player combination.

The data processing functions included in a handheld device may require a variety of input/output capabilities.

10 Devices with audio signal processing capabilities require a microphone for input and/or a speaker for output. Tactile transducers such as keypads and touch panel displays are useful for general alphanumeric input to a wide variety of devices. Visual displays ranging from simple indicating

15 lights to video displays capable of rendering a television broadcast may be found as the outputs on many handheld devices.

In addition to user input/output interfaces, devices may

20 also have wireless transmitters and receivers. These wireless interfaces may use radio frequency, infrared, or visible portions of the electromagnetic spectrum.

The competing interests of increasing functionality and small size in handheld devices have led to compromises in the design of the fixed form factor packages that are used for most handheld devices. For example, devices such as

5 calculators or personal digital assistants must allocate a fixed amount of available surface area to a display and a keypad.

Ergonomic constraints also play a key role in the design
10 of fixed form factor handheld devices. The degree of miniaturization that can be applied to a keypad is typically limited by the size and dexterity of an average user's fingers. Likewise, the placement of a speaker and microphone for a telephone is limited by the mouth and ear separation of
15 a typical user.

Fixed form factor handheld devices such have been supplemented by variable form factor devices having components connected by hinges. In general, hinges provide a
20 more compact form factor for storage when closed, but the device is often not functional with the hinge in a closed position (e.g., a some handheld calculators).

Conventional placements of speakers, microphones, and keyboards (keypads) yielded larger PDA form factors and resulted in undesirable telephony experiences while also not addressing issues relating to an integrated display

5 protection solution. Displays were left exposed and unprotected from debris and facial oils during phone usage.

Many integrated keyboards are forced to fit within the width of a portrait-mode device, thus compromising ergonomics due to decreased key size and spacing. Further, earpiece to
10 microphone separations were solely dictated by device size, whether too small or too large.

Thus, a need exists for an adjustable form factor for handheld devices that provides functionality in both extended
15 and compact forms.

SUMMARY OF INVENTION

Accordingly, several embodiments of the present invention include structures that provide a handheld data processing device with functionality in a variety of forms.

The input and output characteristics for the device are adjustable by the user through variations of the form factor of the handheld device.

A handheld data processing device having three functional components assembled in a sliding configuration is disclosed. A processor module is mechanically coupled to two sliding covers. The processor module houses circuits for performing the functions of data processing and may also

include a display and input/output functionality. The two sliding covers provide protection for the processor module (including display screen) and may include input/output transducers such as a keypad, speaker or microphone.

Embodiments of the handheld data processing device include a handheld computer, wireless telephone and handheld video display.

P A T E N T
T R A C K E R

In an embodiment of the present invention, housed as a handheld computer, the display and processing functions are integrated within a display/processor module and two keypad sliders provide a keypad for input. The keypad sliders may 5 slide in a plane parallel to the surface of the display and may adjusted to shield or expose the display by sliding. One or both of the keypad sliders may include a transparent window that enables viewing of the display while in the closed position. In one embodiment, a "QWERTY" keypad with 10 control and option keys is provided.

In another embodiment of the present invention, a wireless telephone, the display and processing functions are housed in a transceiver module and the two keypad sliders 15 provide a keypad for input. One of the two keypad sliders houses a microphone and the other houses a speaker. The two sliders are capable of sliding independently of one another and allow for adjustment of the microphone and speaker separation distance. Additionally, one or more detent 20 mechanisms may be provided to provide for setting a repeatable and stable microphone and speaker separation distance. In this embodiment, the speaker and microphone may

be located on the side of the device that is opposite of the display.

The invention separates the traditional handheld computer component package into three distinct elements that reconfigure relative to each other through a sliding mechanism. The articulating left/right side element may house numerical dialer keys for telephony functionality, full QWERTY keyboard, and navigation/application keys on the front of the device and speaker and microphone on the rear of the device. The center, fixed element may house the display/PCB/battery, etc.

The left/right housing may slide over a majority of the display module in the closed position. Advantages to this articulation are:

decreased overall length of the product for compact storage, one handed telephony usage, and/or keyboard input; protection of the display from debris and sharp objects during storage;

protection of the display from facial oils and chemicals during telephony modes when device is placed against face and ear;

provides a more ergonomically oriented keyboard design
for data input/retrieval and telephone dialing that is
accessible whether device is open or closed;
partially exposed display is convenient for minimal PDA
5 and/or telephony information display.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and form a part of this specification, illustrate embodiments of
5 the invention and, together with the description, serve to explain the principles of the invention:

Figure 1 shows a handheld data processing device with a
sliding form factor in an open position in accordance with an
10 embodiment of the present claimed invention.

Figure 2 shows the handheld data processing device with a sliding form factor in a closed position in accordance with an embodiment of the present claimed invention.

15

Figure 3A shows a handheld data processing device with a sliding form factor in portrait display mode in accordance with an embodiment of the present claimed invention.

20 Figure 3B shows a handheld data processing device with a sliding form factor in portrait display mode in accordance with an embodiment of the present claimed invention.

Figure 4A shows a handheld wireless telephone with a sliding form factor in an open position in accordance with an embodiment of the present claimed invention.

5 Figure 4B shows a handheld wireless telephone with a sliding form factor in a closed position in accordance with an embodiment of the present claimed invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In the following detailed description of the present invention, an integrated handheld data processing device having a sliding form factor, numerous specific details are set forth in order to provide a thorough understanding of the present invention. However, it will be obvious to one skilled in the art that the present invention may be practiced without these specific details. In other instances well known methods, procedures, components, and circuits have not been described in detail so as not to unnecessarily obscure aspects of the present invention.

Figure 1 shows a handheld data processing device with a sliding form factor in an open position in accordance with an embodiment of the present invention. The handheld device has three basic components: a processor/display module 100, a first slider 101 and a second slider 102.

Each of the three basic components may house a unique set of functions. General examples of the functions that may be housed in a processor display module or a slider will be provided below.

PROVISIONAL
PATENT
APPLICATION

Further examples of functionality and construction may be found in U.S. Patent application No. 09/932,213, "Handheld Computer Having Moveable Segments That Can Be Adjusted to 5 Affect a Size of the Handheld Computer", filed August 17, 2001; which is incorporated herein by reference.

It should be noted that a slider or display/processor module 100 incorporated in a handheld data processing device 10 in accordance with the present invention may have more or less functionality than the following examples. For example, a slider of a particular handheld device may be described as having a keypad, a microphone, and a window; but may just as well have only one of the named elements in accordance with 15 the spirit of the invention. A keypad may be provided with a "QWERTY" style keyboard with control, function and option keys.

The functionality of the display/processor module 100 20 may include a microprocessor and memory for storage of data and instructions. The microprocessor may be a general purpose processor with a complex instruction set computer (CISC) architecture or a reduced instruction set computer (RISC)

architecture. A CISC or RISC processor is preferable for handheld computers that are focused on text and numeric processing. Alternatively, the processor may include a digital signal processor (DSP) for audio processing and

5 analog-to-digital (A/D) or digital-to-analog (D/A) conversion capability. A DSP may serve as the front end processor for a voice recognition capability and may be combined with a RISC or CISC processor. Other processing capabilities that may be included are formatting (or coding) and modulation for

10 wireless transmission, as well the complementary processing required for wireless reception.

The types of input that may be processed by processor/display module 100 include audio, keypad entries,

15 touch display screen entries, and electromagnetic signals. Some of these types of input may be accepted directly by the processor (e.g., electromagnetic signals or touch display screen entries), while others may be received from a slider (e.g., audio or keypad entries).

20

The processor/display module 100 may include a display area 106 such as a liquid crystal display (LCD), field emission display (FED), electronic paper, or other display

with a thin form factor. For use as a video display for stored programs material or wireless reception, a fast display such as field emission display is preferred.

5 The display 106 may also be capable of accepting input as a touch panel display. Touch panel displays are typically multilayer structures combining a transparent means of sensing the position and possibly the magnitude of a contact local to the display surface with an underlying display. The
10 overall display 106 may have a graffiti area 107 capable of accepting handwritten input. The display 106 may also have icons 108 that respond to touch.

15 One function of sliders 101 and 102 is to protect the display/processor module 100, as shown by Figure 2. In the closed position, the two sliders completely cover the upper surface of the processor/display module 100. Each slider may have a transparent window 104, preferably made from an impact and scratch resistant polymer. In the closed position shown
20 in Figure 2, the windows 104 provide partial visibility of the display while protecting the display.

The display driver of the device may be sensitive to
the relative position of the sliders with respect to the
display/processor module, and automatically adjust the area
of the display used for output to match the visible area of
5 the window region 104. For the configuration of Figure 2, the
area of the display used would be limited to the area visible
through the windows 104. If a touch panel display is used
with software generated icons, the icons may be automatically
shifted in accordance with the slider position so that they
10 remain accessible to the user.

Figure 2 also shows a slightly modified QWERTY layout in
which the standard key positions have been shifted in order
to allow the layout to be separated into two halves, while
15 occupying minimum space.

Referring again to Figure 1, slider 101 and slider 102
each include a keypad and thus are examples of a keypad
slider. A membrane keypad may be preferred. Drive current and
20 signals generated by the keypad may be coupled to the
display/processor 100 by a flexible ribbon connector or
sliding contacts. Alternatively, signals between the sliders

and display processor 100 may be optically coupled (e.g., a light emitting diode and detector pair).

Figure 3A shows a handheld data processing device with a
5 display 300 that has a display orientation controller. The display orientation controller selects between two orthogonal display modes (e.g., portrait and landscape.) The portion of text 301 is displayed in portrait mode in Figure 3A, whereas Figure 3B shows a display 300 with a portion of text 303 that
10 is displayed in landscape mode. It is appreciated that the display or portrait or landscape mode may be selected based on a user command, or, it may be automatically selected based on the orientation of the device.

15 The display 300 may also include a line selection driver for executing commands by using a slider to reference a line on the display. As shown in Figure 3A, a "macro command" 302 is aligned with the edge of a slider 312 and is therefore selected. A macro command is a character string that refers
20 to an executable command or series of commands. For example, the character string may be an email address or telephone number that may be selected for sending an email or initiating a telephone call. Once selected, the macro command

may be executed by appropriate input (e.g., a keystroke or contact with a touch panel display).

Figure 4A shows a rear view of the handheld wireless

5 device, e.g., here a telephone, with a sliding form factor in an open position in accordance with an embodiment of the present claimed invention. The telephone has three basic components: a transceiver module 400, a first slider 401 and a second slider 402. The three components are similar to the 10 three components shown in Figure 1, and the wireless telephone may of Figure 4A may be integrated with the data processing device of Figure 1, with Figure 4A providing a rear view of the integrated device to complement the front view provided by Figure 1.

15

The first slider 401 includes a microphone 403 and is electrically and/or optically coupled to the transceiver module 400. The sliding interface between the slider 401 and the transceiver module 400 preferably incorporates a detent 20 mechanism to enable repeatable and stable positioning of the slider 401 with respect to the transceiver module 400. In an integrated device, the microphone may also serve as an input device for voice recognition or recording.

The second slider 402 includes a speaker 404 and is electrically and/or optically coupled to the transceiver module 400. The sliding interface between the slider 401 and 5 the transceiver module 400 preferably incorporates a detent mechanism to enable repeatable and stable positioning of the slider 402 with respect to the transceiver module 400. In an integrated device, the speaker may also serve as an output for stored audio program material or real-time broadcast 10 audio material.

Figure 4B shows a handheld wireless telephone with a sliding form factor in a closed position in accordance with an embodiment of the present claimed invention. For an 15 integrated device, the view shown in Figure 4B corresponds to the view shown in Figure 2, wherein the front side of the integrated device is represented by Figure 2 and the back side is represented by Figure 4B.

20 In the integration of a wireless telephone and a data processing device with a display, there is a distinct advantage in allocating the telephony functions to the side opposite of the display side. Contact between a user's skin

will tend to contaminate the a display surface, and contact
between the user and the telephone is typically desirable in
order to enhance the intelligibility of conversation and
screen out ambient noise. In addition to the microphone 403
5 shown on slider 401, a second microphone may be included on
the opposite side in an integrated device so that audio input
such as speech could be input while looking at a display. In
order to reduce noise, one microphone or the other may be
automatically selected by the application that is currently
10 being used (e.g., telephony or voice commands).

The foregoing descriptions of specific embodiments of
the present invention have been presented for purposes of
15 illustration and description. They are not intended to be
exhaustive or to limit the invention to the precise forms
disclosed, and obviously many modifications and variations
are possible in light of the above teaching. The embodiments
were chosen and described in order to best explain the
20 principles of the invention and its practical application, to
thereby enable others skilled in the art to best utilize the
invention and various embodiments with various modifications
are suited to the particular use contemplated. It is intended

that the scope of the invention be defined by the Claims appended hereto and their equivalents.
